

Departmental Store Sales Analytics Dashboard

Project Overview

This project involved designing and developing an interactive Power BI dashboard to analyze and monitor sales performance for a departmental store. The goal was to transform raw transactional data into meaningful insights that support data-driven business decisions.

Key Objectives

- Track overall revenue, profit, and growth trends.
- Analyze product category performance and top-selling items.
- Identify regional and monthly sales patterns.
- Support inventory planning and strategic decision-making.

Data Preparation & Modeling

The raw sales data was cleaned and transformed using Power Query. Data types were standardized, missing values handled, and necessary transformations applied to ensure consistency. A structured data model was built by creating relationships between tables, optimizing performance and enabling accurate analysis.

Dashboard Development

- Created DAX measures for KPIs including Total Sales, Profit, and Growth %.
- Designed interactive visuals for category-wise, monthly, and regional analysis.
- Developed dynamic filters and slicers for user-driven exploration.
- Highlighted top-performing products and underperforming segments.

Business Impact

The final dashboard enables stakeholders to monitor store performance in real-time, identify trends quickly, and make informed decisions regarding inventory management, pricing strategies, and revenue growth initiatives.
